1 Data description

The data can be found on kaggle.com: Urinary biomarkers for pancreatic cancer The files are saved as Data.csv and Documentation.csv for easier access.

The following packages were used:

- dplyr
- readr
- pander
- FSA
- ggplot2
- \bullet ggpubr
- ggbiplot

2 Reading the data

We first want to create an insight of our data:

```
dataset <- read.csv("../data/Data.csv")
codebook <- read_delim("../data/codebook.txt", delim = "|")
pander(codebook[1:4], booktabs = T, caption = "Data values", split.tables = 100)</pre>
```

Table 1: Data values

Name	Full Name	Type	Unit
sample_id	Sample ID	chr	-
$patient_cohort$	Patient's Cohort	chr	-
$\operatorname{sample_origin}$	Sample Origin	chr	-
age	Age of subject	dbl	-
sex	Sex of subject	chr	-
$\operatorname{diagnosis}$	Diagnosis	dbl	-
stage	Stage	chr	-
benign_sample_diagnosis	Benign Sample's Diagnosis	chr	-
$plasma_CA19_9$	Blood plasma CA19-9	dbl	U/ml
creatinine	Creatinine	dbl	m mg/ml
LYVE1	LYVE1	dbl	ng/ml
REG1B	REG1B	dbl	ng/ml
$\mathrm{TFF1}$	TFF1	dbl	ng/ml
REG1A	REG1A	dbl	ng/ml

Table 2: Description

Name	Description
sample_id	Unique string identifying each subject
patient_cohort	Cohort 1 = previously used samples; Cohort 2 = newly added samples
$sample_origin$	BPTB: Barts Pancreas Tissue Bank, London,
	UK; ESP: Spanish National Cancer Research
	Centre, Madrid, Spain; LIV: Liverpool
	University, UK; UCL: University College
	London, UK
age	Age in years
sex	M = male; F = female
diagnosis	1 = control (no cancer); 2 = benign
	hepatobiliary disease; $3 = PDA$ (pancreatic cancer)
stage	The stage of the disease (IA, IB, IIA, IIB, III, IV)
benign_sample_diagnosis	The diagnosis for those with a benign diagnosis
plasma_CA19_9	Blood plasma levels of CA19-9 monoclonal antibody, usually elevated when pancreatic cancer
creatinine	Urinary biomarker of kidney function

Name	Description
LYVE1	v v 1
REG1B	Endothelial Hyaluronan receptor 1 Urinary levels of Regenerating Family Member 1 Beta
TFF1 REG1A	Urinary levels of Trefoil Factor 1 Urinary levels of Regenerating Family
	Member 1 Alpha

The information given in the codebook originates from the <code>Documentation.csv</code>. This file was given with the data file and can be found on the website.

3 Manipulate the data

A lot of the rows contain empty strings instead of NA, which has to be fixed first. Besides that, the columns sample_id, patient_cohort, sample_origin, and benign_sample_diagnosis in the dataset significant value for the analysis and are therefor dropped. A column diagnosis_group was added for a comparison test.

```
# Change the empty strings to NA
dataset[dataset == ""] <- NA</pre>
# Remove unnecessary columns
drop <- c("sample_id", "patient_cohort", "sample_origin", "benign_sample_diagnosis")</pre>
dataset <- dataset[,!(names(dataset) %in% drop)]</pre>
# Group the samples
dataset <- dataset %>%
  mutate(
    ## Factor for order of age
    diagnosis_group = factor(
      dplyr::case_when(
        diagnosis == 1 ~ "Control",
        diagnosis == 2 ~ "Benign",
        stage == "I" ~ "I-IIA",
        stage == "IA" ~ "I-IIA",
        stage == "IB" ~ "I-IIA",
        stage == "II" ~ "I-II",
        stage == "IIA" ~ "I-IIA",
        stage == "IIB" ~ "I-II",
        stage == "III" ~ "III-IV",
        stage == "IV" ~ "III-IV" ),
      level = c("Control", "Benign", "I-IIA", "I-II", "III-IV")
  )
# Perform the tests
REG1A <- dunnTest(dataset$REG1A ~ dataset$diagnosis_group)</pre>
REG1B <- dunnTest(dataset$REG1B ~ dataset$diagnosis_group)</pre>
# Create a nice format to show the correct comparisons
comparison <- t(cbind(REG1A\$res[c(2:5,7,8),c(1,4)], REG1B\$res[c(2:5,7,8),4]))
colnames(comparison) <- comparison[1,]</pre>
comparison <- comparison[-1,]</pre>
comparison <- apply(comparison, 2, as.numeric)</pre>
rownames(comparison) <- c("REG1A", "REG1B")</pre>
comparison[comparison > 0.05] <- "ns"</pre>
dataset <- dataset[,!(names(dataset) %in% "REG1A")]</pre>
```

3.1 REG1A vs. REG1B

Although performance between the two is similar, a Kruskal-Wallis test with Dunn's multiple comparisons shows that REG1B outperforms REG1A when the control and benign samples are compared to the I-IIA PDAC samples. Therefor, REG1B was used further on in the experiments and REG1A is dropped.

3.2 Log transformation

A summary of the data shows very high maximum values, but rather low medians. A log-transformation is applied to correct this.

pander(summary(dataset), split.table = 100)

Table 3: Table continues below

age	sex	diagnosis	stage	plasma_CA19_9
Min. :26.00	Length:590	Min. :1.000	Length:590	Min.: 0.0
1st Qu.:50.00	Class:character	1st Qu.:1.000	Class:character	1st Qu.: 8.0

NA	NA	NA	NA	NA

```
log.data <- log(dataset[5:9] +1)
dataset[5:9] <- log.data</pre>
```

The samples are then grouped by diagnosis for easier access of the different samples. Table 5 shows the different amounts of samples per diagnosis and the amount of which are also blood samples. After the blood samples are separated the column can be dropped.

```
# Different diagnosis and blood groups
control <- subset(dataset, diagnosis == 1)</pre>
benign <- subset(dataset, diagnosis == 2)</pre>
pdac <- subset(dataset, diagnosis == 3)</pre>
blood <- subset(dataset, plasma_CA19_9 >= 0)
# Drop the "plasma" column
dataset <- dataset[,-5]</pre>
# Demographics
demograph <- data.frame(c(sum(control$sex == "F"), sum(control$sex == "M")),</pre>
                         c(sum(benign$sex == "F"), sum(benign$sex == "M")),
                         c(sum(pdac$sex == "F"), sum(pdac$sex == "M")))
blood.demo <- data.frame(c(sum(blood$sex == "F" & blood$diagnosis == 1),
                            sum(blood$sex == "M" & blood$diagnosis == 1)),
                          c(sum(blood$sex == "F" & blood$diagnosis == 2),
                            sum(blood$sex == "M" & blood$diagnosis == 2)),
                          c(sum(blood$sex == "F" & blood$diagnosis == 3),
                            sum(blood$sex == "M" & blood$diagnosis == 3)))
colnames(blood.demo) <- c("Control", "Benign", "PDAC")</pre>
colnames(demograph) <- c("Control", "Benign", "PDAC")</pre>
demograph <- rbind(demograph, blood.demo)</pre>
rownames(demograph) <- c("Female total", "Male total", "Female blood", "Male blood")</pre>
pander(demograph, booktabs = T, caption = "Demographic of the samples",
       justify = c("left", "center", "center", "center"))
```

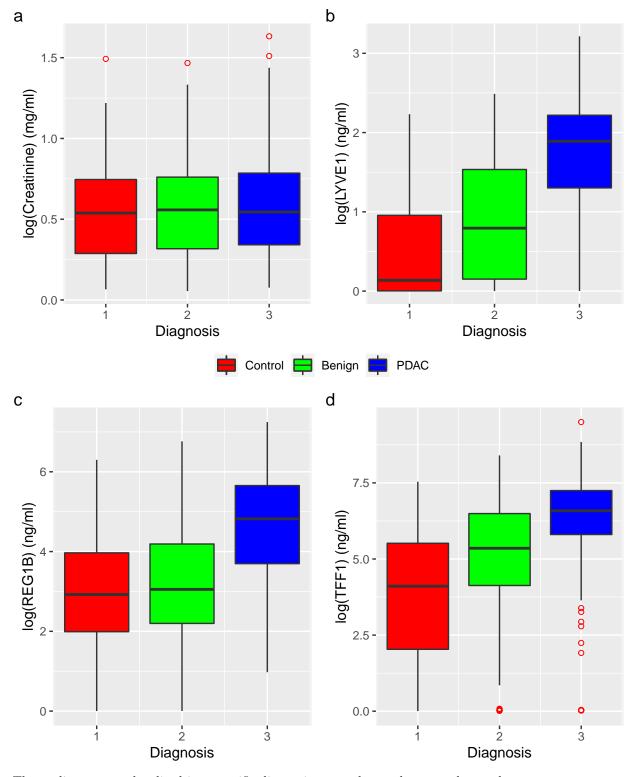

Table 5: Demographic of the samples

	Control	Benign	PDAC
Female total	115	101	83
Male total	68	107	116
Female blood	58	57	64
Male blood	34	51	86

4 Analyse the data

4.1 Boxplots

```
# Boxplot function
create.plots <- function(y.values, y.label, plt.tag) {</pre>
  list(ggplot(data = control, aes(x = diagnosis, y = !!sym(y.values))) +
    geom_boxplot(outlier.color = "red", outlier.shape = 1, aes(fill = "Control")) +
    geom_boxplot(data = benign, outlier.color = "red", outlier.shape = 1,
                 aes(fill = "Benign")) +
    geom_boxplot(data = pdac, outlier.color = "red", outlier.shape = 1,
                 aes(fill = "PDAC")) +
    labs(x = "Diagnosis", y = y.label, tag = plt.tag) +
    scale_fill_manual(values = c("red", "green", "blue"),
                      limits = c("Control", "Benign", "PDAC"),
                      name = ""))
}
# Create the boxplots for the different columns
y.values <- names(dataset[5:8])</pre>
y.labs <- c("log(Creatinine) (mg/ml)", "log(LYVE1) (ng/ml)", "log(REG1B) (ng/ml)",
            "log(TFF1) (ng/ml)")
plt.tag <- c("a", "b", "c", "d")
plts <- mapply(create.plots, y.values, y.labs, plt.tag)</pre>
# Grid and print the plots
p1 <- ggarrange(plotlist = plts[1:2], ncol = 2,
                common.legend = TRUE, legend = "bottom")
p2 <- ggarrange(plotlist = plts[3:4], ncol = 2,</pre>
                common.legend = TRUE, legend = "none")
my.grid <- ggarrange(p1, p2, nrow = 2)</pre>
print(annotate_figure(my.grid))
```

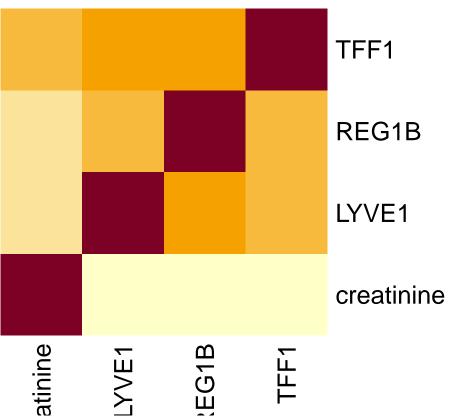

The outliers are not localized in a specific diagnosis group, but rather spread over the groups.

4.2 Correlation matrix

```
cor_matrix <- cor(dataset[,5:8])
heatmap(cor_matrix, scale = "column", Colv = NA, Rowv = NA, main = "Correlation matrix")</pre>
```

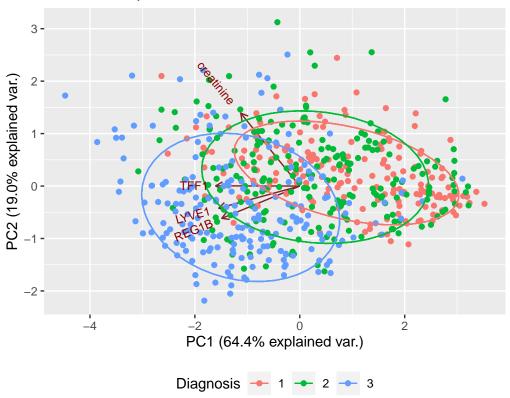

Correlation matrix

The heatmap shows that there is not much correlation between creatinine and the other variables. The other outstanding one has to be the TFF1 biomarker, being the most correlated variable to others.

4.3 PCA

PCA of complete dataset

While the control and benign group show relative distance from the PDAC group, there is a still a lot of overlapping samples with the benign and PDAC groups. As earlier concluded from the heatmap, the creatinine biomarker does not show much relativeness with the other biomarkers. LYVE1 is nicely in between the TFF1 and REG1B biomarkers. Every point close tho the origin have values close to the mean for all variables.

5 Machine Learning

5.1 Model exploration

For the exploration of the model, the data is cleaned it contains only the biomarkers and the classification labels (Control, Benign, I-II, and III-IV). For the code used to prepare the data, see

cleaned <- read.csv("../data/cleaned_data.csv")
pander(head(cleaned))</pre>

age	sex	plasma_CA19_9	creatinine	LYVE1	REG1B	TFF1	diagnosis_group
33	\mathbf{F}	2.542	1.041	0.6383	3.988	6.485	Control
81	\mathbf{F}	NA	0.6794	1.111	4.559	5.349	Control
51	\mathbf{M}	2.079	0.5768	0.1359	4.638	6.136	Control
61	\mathbf{M}	2.197	0.5313	0.002801	4.12	4.969	Control
62	\mathbf{M}	2.303	0.1947	0.0008592	4.198	3.74	Control
53	M	NA	0.6142	0.003387	4.145	4.107	Control

To set a baseline, the data is run through different types of algorithms in Weka:

NaiveBayes

Table 7: Results algorithm comparison in Weka, '*' = significantly worse; 'v' = significantly better

Algorithm	Accuracy	Sensitivity	Specificity	ROC	FNR
ZeroR	35.25%	0.00	1.00	0.50	1.00
OneR	41.19% v	0.48 v	0.78 *	0.63 v	0.52 *
NaiveBayes	$48.66\%~\mathrm{v}$	0.57 v	0.80 *	0.82 v	0.43 *
SimpleLogistics	$53.36\%~\mathrm{v}$	0.53 v	0.83 *	0.82 v	0.47 *
SMO	51.93% v	0.42 v	0.88 *	$0.78 \mathrm{\ v}$	0.58 *
IBk	43.25% v	0.39 v	0.89 *	$0.64 \mathrm{\ v}$	0.58 *
J48	$48.44\%~\mathrm{v}$	0.58 v	0.78 *	$0.78 \mathrm{\ v}$	0.42 *
RandomForest	55.54% v	0.66 v	0.82 *	0.85 v	0.34 *

These results show a relative low sensitivity and high FNR. Some algorithms have a low ROC value, low sensitivity and low accuracy: OneR, IBk, and J48 are not further analysed. OneR will be kept to set a baseline. The SMO algorithm has a low sensitivity and the highest FNR, therefor also dropped.

Table 8: Confusion matrix per algorithm

SimpleLogistics

b	c	d	classified as	a	b	c	d	classified as
